

ABSTRACT

A pump container comprising a container body, discharging pump and a movable bottom part, configured so as to prevent air
5 from being taken into the container body by allowing, when contents
are discharged by pumping operation, the bottom part to move upward
by the volume of the contents discharged by pumping operation,
wherein the pump container comprises a main container and an
auxiliary container separated from the main container by a
10 separating means, and through operation, the separating means
allows the constitution of a communication between the main
container and the auxiliary container to allow mixing of the
contents of the both containers.
